Overview

° Virtual Memory
° Page Table

Cache Review (#1/2)

° Caches are NOT mandatory:
  • Processor performs arithmetic
  • Memory stores instructions & data
  • Caches simply make things go faster

° Each level of memory hierarchy is just a subset of next lower level

° Caches speed up due to Temporal Locality: store data used recently

° Block size > 1 word speeds up due to Spatial Locality: store words adjacent to the ones used recently

Cache Review (#2/2)

° Cache design choices:
  • size of cache: speed vs. capacity
  • direct-mapped vs. associative
  • for N-way set assoc: choice of N
  • block replacement policy
  • 2nd level cache?
  • Write through vs. write back?

° Use performance model to pick between choices, depending on programs, technology, budget, ...
Another View of the Memory Hierarchy

Virtual Memory

If Principle of Locality allows caches to offer (usually) speed of cache memory with size of DRAM memory, then why not, recursively, use at next level to give speed of DRAM memory, size of Disk memory?

Called “Virtual Memory”
- Also allows OS to share memory, protect programs from each other
- Today, more important for protection vs. just another level of memory hierarchy
- Historically, it predates caches

Problems Leading to Virtual Memory (#1/2)

- Programs address space is larger than the physical memory.
  - Need to swap code and data back and forth between memory and Hard disk using Virtual Memory

Problems Leading to Virtual Memory (#2/2)

- Many Processes (programs) active at the same time. (Single Processor - many Processes)
  - Processor appears to run multiple programs all at once by rapidly switching between active programs.
  - The rapid switching is managed by Memory Management Unit (MMU) by using Virtual Memory concept.
  - Each program sees the entire address space as its own.
  - How to avoid multiple programs overwriting each other.
Segmentation Solution

- Segmentation provides simple MMU
  - Program views its memory as a set of segments. Code segment, Data Segment, Stack segment, etc.
  - Each program has its own set of private segments.
  - Each access to memory is via a segment selector and offset within the segment.
  - It allows a program to have its own private view of memory and to coexist transparently with other programs in the same memory space.

Segmentation Memory Management Unit

- Virtual Address to memory
- Look up table held by OS in mem
- Segment Descriptor Table (SDT)
  - Base: The base address of the segment
  - Logical address: an offset within a segment
  - Bound: Segment limit
  - SDT: Holds Access and other information about the segment

Virtual to Physical Addr. Translation

- Each program operates in its own virtual address space;
- Each is protected from the other
- OS can decide where each goes in memory
- Hardware (HW) provides virtual -> physical mapping

Simple Example: Base and Bound Reg

- User A
- User B
- User C
- OS

- Enough space for User D, but discontinuous (“fragmentation problem”)
- Want discontinuous mapping
- Process size >> mem
- Addition not enough!
Mapping Virtual Memory to Physical Memory

- Divide into equal sized chunks (about 4KB)
- Any chunk of Virtual Memory assigned to any chunk of Physical Memory ("page")

Virtual Memory

- Stack
- Heap
- Static
- Code

Physical Memory

64 MB

Paging Organization (assume 1 KB pages)

Physical Address | Page is unit of mapping | Virtual Address
---|---|---
0 page 0 | 1K | 0
1024 page 1 | 1K | page 1
2048 page 2 | 1K | page 2
31744 page 31 | 1K | page 31

Virtual Memory

Virtual Address Mapping: Page Table

- Cannot have simple function to predict arbitrary mapping
- Use table lookup of mappings
  - Page Number | Offset
  - Use table lookup ("Page Table") for mappings: Page number is index
  - Virtual Memory Mapping Function
    - Physical Offset = Virtual Offset
    - Physical Page Number = PageTable[Virtual Page Number]
      (P.P.N. also called "Page Frame")

Address Mapping: Page Table

- Page Table located in physical memory
- Page Table Base Reg
- Reg #2 in CP #15 in ARM
- (actually, concatenation)
Page Table

- A page table is an operating system structure which contains the mapping of virtual addresses to physical locations.
  - There are several different ways, all up to the operating system, to keep this data around.
- Each process running in the operating system has its own page table.
  - "State" of process is PC, all registers, plus page table.
  - OS changes page tables by changing contents of Page Table Base Register.

Page Table Entry (PTE) Format

- Contains either Physical Page Number or indication not in Main Memory
- OS maps to disk if Not Valid \( V = 0 \)

<table>
<thead>
<tr>
<th>Page Table</th>
<th>V</th>
<th>A.R.</th>
<th>P. P.N.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Val</td>
<td></td>
<td>Access Rights</td>
<td>Physical Page Number</td>
</tr>
<tr>
<td></td>
<td>V</td>
<td>A.R.</td>
<td>P. P. N.</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- If valid, also check if have permission to use page: **Access Rights** (A.R.) may be Read Only, Read/Write, Executable

Things to Remember

- Apply Principle of Locality Recursively
- Manage memory to disk? Treat as cache
  - Included protection as bonus, now critical
  - Use **Page Table** of mappings vs. tag/data in cache
- Virtual Memory allows protected sharing of memory between processes with less swapping to disk, less fragmentation than always swap or base/bound
- Virtual Memory allows protected sharing of memory between processes with less swapping to disk, less fragmentation than always swap or base/bound in Segmentation
